*Tutor:*

Riemer van Rozen

*Course:*

Software Evolution

## 1 Introduction

This documents contains our notes and answers to the questions about software metrics (practical lab Series 2).

Rewrite the introduction

## 2 Definitions

In order to provide a tool to satisfy the assignment's objectives, a good understanding of the key concepts used in clone detection is needed. Based on a biref literature study, we have selected the following definitions as the base for our work and evaluation of the cloning problem:

### 2.1 Clones and clone classes

- **Clone relation** is an equivalence relation on code portions [2].
- **Clone pair** is a set of two code portions that are in clone relation with each other (compare [2]).
- **Clone class** is an equivalence class of clone relation. In other words, it is a set of multiple (more than one) code portions which hold mutual clone relation to each other (compare [2]).
- **The biggest clone** is is the biggest (has the largest number of lines of code) code portion, for which exists at least one code portion, which holds clone relation with it.
- **The biggest clone class** is the biggest equivalence class of clone relation (has the most elements) in the domain of examined project.

### 2.2 Clone types

- **Type-1 clones** are per definition from [3] strict textual clones, excluding comments and white spaces.

- **Type-2 clones** are definition from [3] *a syntactically identical copy; only variable, type, or function identifiers have been changed.*
- **Type-3 clones** are per definition from [3] copies with further changes like adding/removing statements.

### 3 Algorithm design

- Describe how the algorithm is covered in the literature (and provide references).

#### 3.1 General algorithm design

The idea and algorithm of our duplication detection is based on the information from [4] and [1]. The main idea behind this approach is to use the abstract syntax tree for clone detection. After creating the AST from the source files, the nodes are hashed into different buckets. If a bucket has more than one element, it follows, that there are multiple locations in the source code of this node. This counts as one clone class. There are multiple types of clones that our tool can detect. These are type 1 and type 2 clones.

For our implementation we only consider nodes that are bigger than a certain threshold. The size of a node is computed by simply counting all the sub-nodes of the node in question. The threshold is a parameter and can be specified when starting the clone detection.

#### 3.2 Type-1 cleaning

**@Cornelius:** This text is difficult to read. Could you rephrase it?

If using the AST approach, the bucket key is in general just the node itself. With rascal though, there was a change in the implementation that shifted the `loc` and other informations of a node from the annotations on the node, to information contained in the node. This messed up the matching because every location was unique, which resulted in every node (because of sub-nodes) being unique. To circumvent the problem we remove the unnecessary information from all the relevant nodes. The actual cleaning `cleanNode` is done by visiting all the sub-nodes of a relevant node and replacing the node with a cleaned version of the original node using the `insert` statement.

#### 3.3 Type-2 cleaning

For type 2 detection we also use the AST. To streamline all the information that is contained in the node we visit all the sub-nodes of a node, and replace specific variables/identifier-s/types with a general one. The replacement is done using the rascal `visit - case =>` notation.

```

1 case Type _ => lang::java::m3::AST::float()
2 case Modifier _ => lang::java::m3::AST::\public()
3 case \method(_, -, a, b) => \method(lang::java::m3::AST::float(), "method", a,
4   b)
5 case \method(_, -, a, b, c) => \method(lang::java::m3::AST::float(), "method",
6   a, b, c)
7 case \parameter(a, -, b) => \parameter(a, "parameter", b)
8 case \vararg(a, _) => \vararg(a, "vararg")
9 case \annotationTypeMember(a, _) => \annotationTypeMember(a, "
10  annotationTypeMember")
11 case \annotationTypeMember(a, -, b) => \annotationTypeMember(a, "
12  annotationTypeMember", b)
13 case \typeParameter(_, a) => \typeParameter("typeParameter", a)
14 case \constructor(_, a, b, c) => \constructor("constructor", a, b, c)

```

```

11 case \interface(-, a, b, c) => \interface("interface", a, b, c)
12 case \class(-, a, b, c) => \class("class", a, b, c)
13 case \enumConstant(-, a) => \enumConstant("enumConstant", a)
14 case \enumConstant(-, a, b) => \enumConstant("enumConstant", a, b)
15 case \methodCall(a, -, b) => \methodCall(a, "methodCall", b)
16 case \methodCall(a, b, -, c) => \methodCall(a, b, "methodCall", c)
17 case \simpleName(-) => \simpleName("simpleName")
18 case \number(-) => \number("125681651")
19 case \variable(-, a) => \variable("variable", a)
20 case \variable(-, a, b) => \variable("variable", a, b)
21 case \booleanLiteral(-) => \booleanLiteral(true)
22 case \stringLiteral(-) => \stringLiteral("stringLiteral")
23 case \characterLiteral(-) => \characterLiteral("a")

```

Listing 1: Node elements stripping method for type-2 clone detection.

### 3.4 The main algorithm

In this section we provide a textual representation of our main algorithm. For further information please take a look into the source file `DuplicationsAnalyzer.rsc`.

```

Build the AST of the project.

For all nodes in AST
- If size of node > threshold
    - Clean node for type 1 detection.
    - Clean node for type 2 detection.
    - Collect node in Map with cleaned node as key,
      relation of original node and location as value

For all keys in Map build a set of clone classes
- Collect all values from the Map for current key
- If size of collected values > 1
    Then
        add values as a new clone class to set

For all previously detected clone classes filter subclone classes
- If another clone class exists for which all locations
  include the locations of the current one
    Then
        -
    Else
        Add to new Set

Collect all filtered clone classes in output format
- Collect locations
- Determine line statistics
- Determine clone type

```

Listing 2: General algorithm pseudocode

## 4 Main program validity

We provide an automatic testing suite to verify that the tool works as designed. To maintain a good separation of concerns between implementation and tests, all tests are in separate

files that extend their original rascal module. This will result in better maintainability, readability and extensibility for the future.

The tests are split in random generated tests where applicable. For example while operating on files and their locations rascal is not able to provide a proper generator for reading the contents of a file. For this we provide three test files that are used in tests where files are needed.

Especially the Clone Detection is covered with random test generators, testing the properties of the tested functions as well as tests where the implementation is tested against the provided test files to assure the continued working in case of refactoring. For design changes the tests may have to be adjusted.

To run the tests, import all the modules below and execute `:test` in the rascal console. The `projectLocation` in `Configuration.rsc` has to be set to the projects location in your eclipse!

- `DuplicationsAnalyzerTests`
- `RaterTests`
- `UtilsTests`
- `VolumeAnalyzerTests`

## 5 The tool

- General description and purpose, used solutions (webserver, REST api, ReactJS app, d3 graphs, etc)
- The 3 main requirements (your tool satisfies from the perspective of a maintainer) [ref to storey1999cognitive]:
  1. Get a comprehensible overview (of code quality and duplications)
    - Readable table
    - SIG maintainability index
  2. Get a deep insight into the clones
    - navigate easily through them
    - provide an extended search function (easy to use = we reduce effort)
  3. See how the clones spread over my project (=Improve comprehension)
    - provide insightful visualization = Provide effective presentation styles (graph)
    - show how the clones containing clones relate to each other (=indicate options for further exploration)
- Implementation choices
- The visualisation (constellation) - how does it help a maintainer or a developer?

## 5.1 Introduction

As it is stated in the assignment, we were supposed to provide a tool for clone detection that we actually would use ourselves. Since web technologies provide currently the best tools to present data and are easy to implement, and since there is a web server in Rascal, we have decided to provide a JavaScript application as the user interface for our tool.

The front-end application is served directly from our Rascal application, which means that no extra configuration is required to use it with the provided clone detector. It is written ReactJS<sup>1</sup>. The main (Rascal) application provides a number of REST API endpoints that the JavaScript application uses to obtain data and request a project analysis.

## 5.2 Requirements

The main requirements that we

## 5.3 Implementation choices

### 5.3.1 Rascal's Web Server REST API

### 5.3.2 Data table

### 5.3.3 Visualization: Constellation

## 6 Tool manual

- How to use
- Where is the Rascal project
- Where is the original visualisation project

To run and use the tool we provide the source code with this report as a eclipse project. The source code for the rascal part of the project can be found at <https://github.com/piotrkosytorz/software-evolution/tree/master/piotr.kosytorz/series1/src/src>. The source code for the visualisation part can be found at <https://github.com/piotrkosytorz/software-evolution/tree/master/piotr.kosytorz/series1/visualisation>.

### 6.1 How to run

In order to run the program, please follow the steps:

1. Please import the project into your eclipse with a working rascal installation.
2. Open `Configuration.rsc` and adjust the location of the `projectLocation` to match the path of the project to your eclipse
3. Do the same for the `smallSqlProject` and `hqSqlProject`
4. Start a rascal console and import the `Main` module
5. run `startServe();`
6. open a browser and point it towards `http://localhost:5433` or to the location of `serveAddress` in case you changed it

## 7 Summary

- Sum things up
- Write how the tool performs on hsqlsb,
- Write how it can be improved
